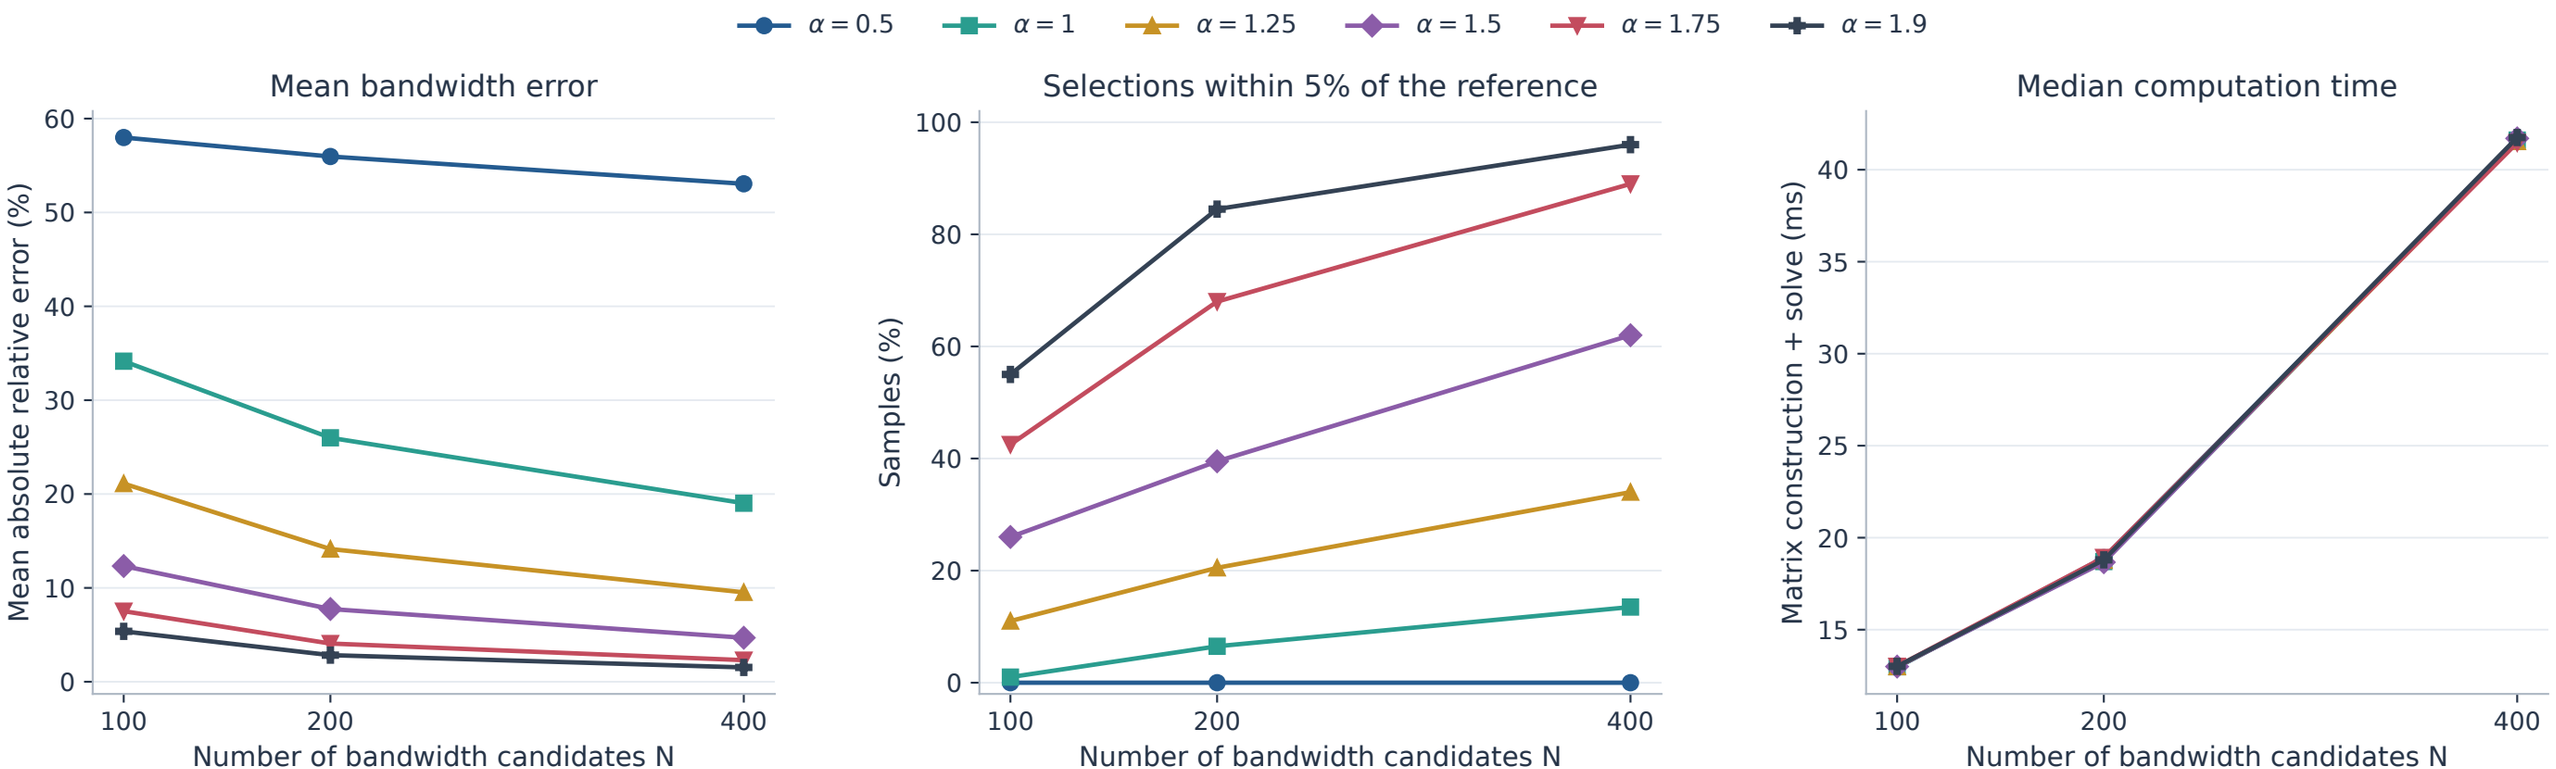
Choosing α across 200 independent samples

Gaussian samples, $n = 200$ | geometric grids on $[0.01, 2]$ | $\lambda_N = N^{\alpha}$ | each sample has its own continuous reference



Paired comparison: all exponents use the same 200 samples. References include both interval endpoints.

Every spectral peak is checked at a finer Fourier resolution. Timings exclude reference searches, validation, plotting and saving.

This experiment measures agreement with the energy minimum; all results concern standard-Gaussian samples of size 200.
