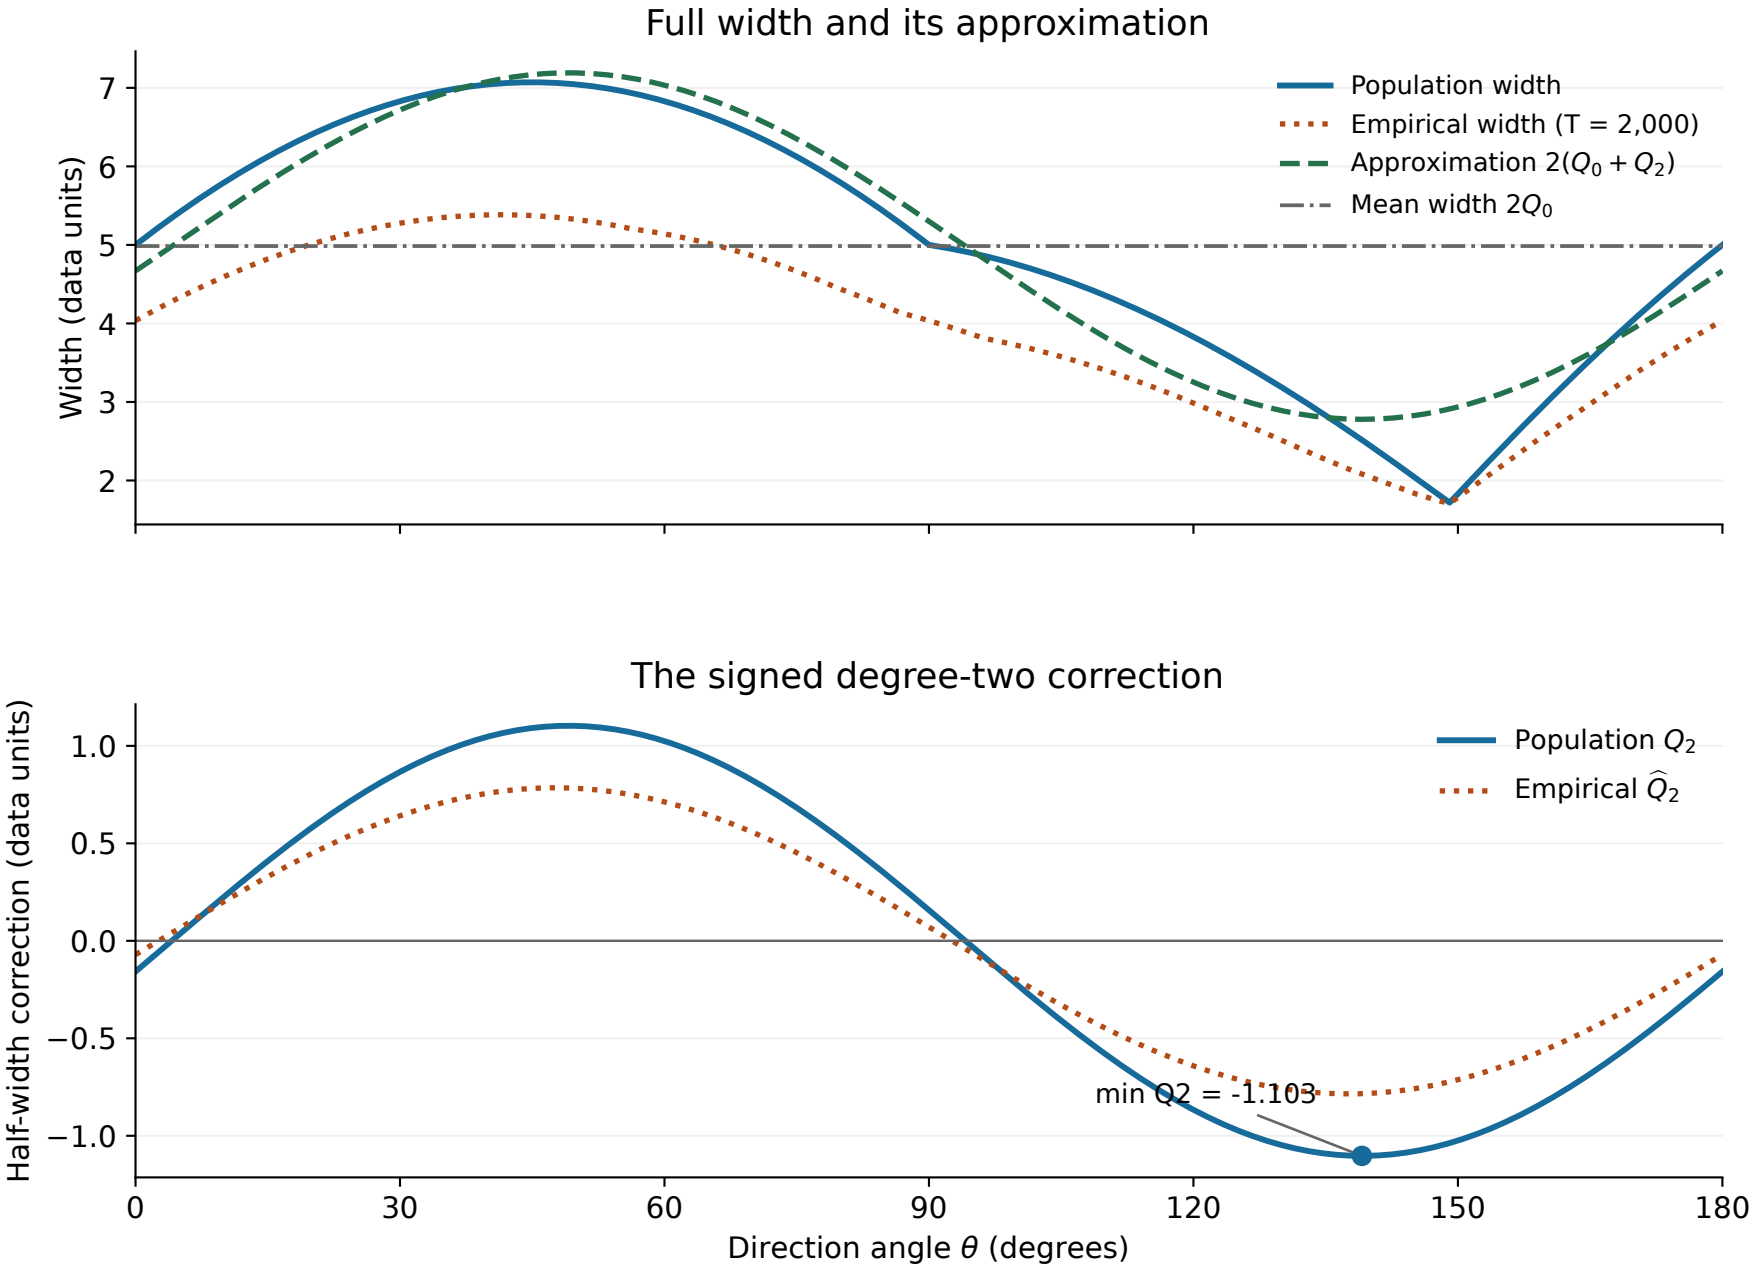
From mean width to the degree-two component

AR(1): coefficient 0.6 | Uniform[-1, 1] innovations | embedding dimension k = 2

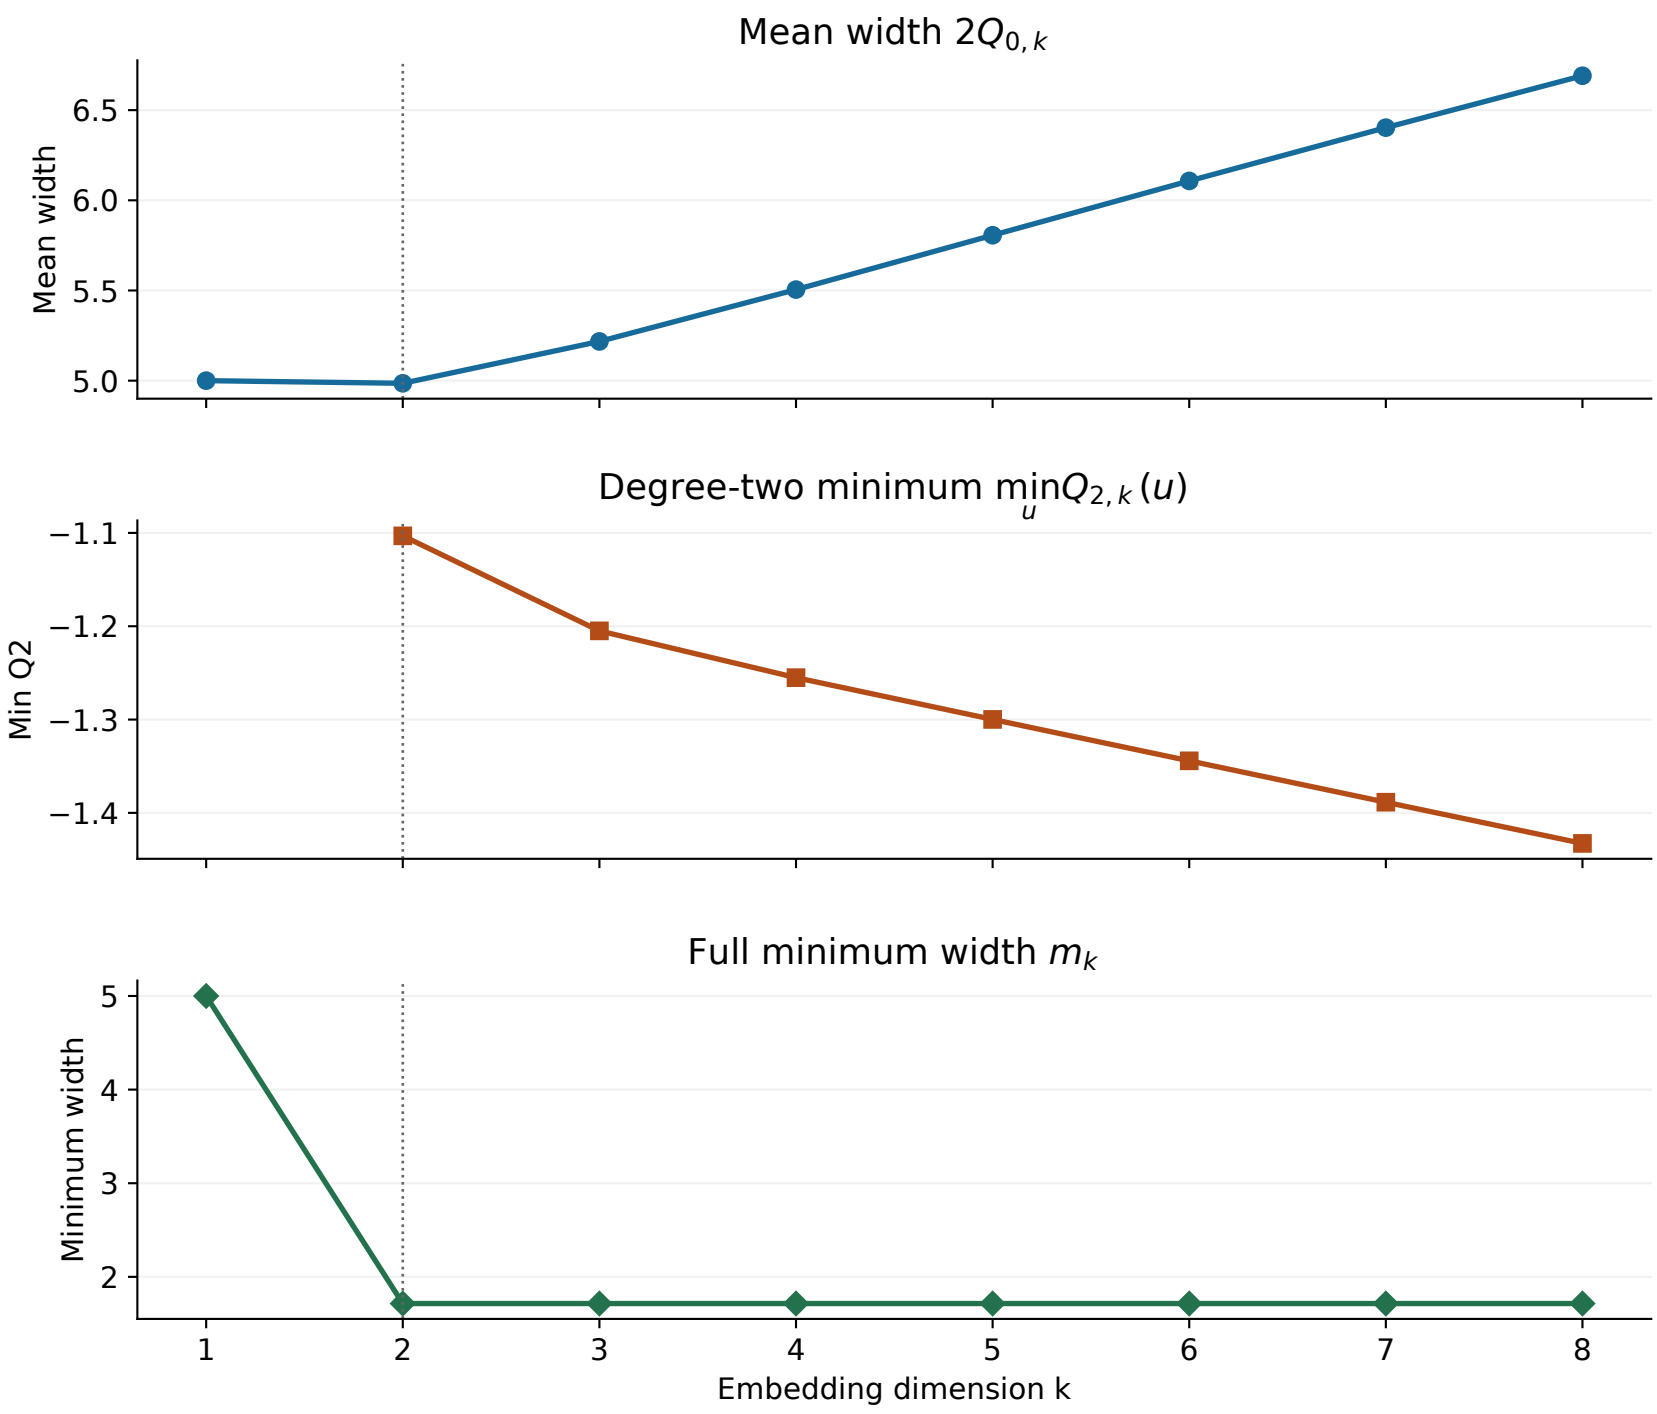


True minimum width: 1.715 Minimum of approximation: 2.779

The degree-two component has angular average zero. Higher components contain the missing detail.

The minimum-width plateau does not transfer to Q2

Same AR(1) model | exact geometric-tail formulas for the population quantities



The dotted line marks k = p + 1 = 2. Only the full minimum width is constant from there.
Q2 is used for k >= 2; its value is a signed correction, with the same physical units as width.
